February 5, 2008

Abstract

This paper provides an alternate derivation of the equations used in the GRMHD code of De Villiers & Hawley using Stokes Theorem. This derivation places the published form of the discretized equations of GRMHD in a broader context, and suggests possible future directions for numerical work.

1 Introduction

The general relativistic magnetohydrodynamic (GRMHD) code of De Villiers & Hawley (2003; DH) has been used to study the accretion of matter onto black holes. It is a highly stable 3 + 1D code that has been used to simulate in great detail the evolution of accretion disks in the spacetime of Kerr black holes. This code has established the ubiquity of energetic axial jets in such environments (De Villiers *et al.*, 2003, 2005), and has shed light on the magnetic environment produced accretion disks (Hirose *et al.*, 2004; De Villiers, 2006).

The refinement of the code through testing and development is ongoing. One area of study that may help spur future improvements is the mathematical foundation of the GRMHD equations. There are many threads in the literature documenting the differential version of the equations. Misner, Thorne, & Wheeler (MTW; 1973) provide a clear derivation of the equations of hydrodynamics. Anile (1989) discusses the extension to magnetohydrodynamics (MHD) in a special relativistic background. Hawley, Smarr, & Wilson (1984; HSW) treat hydrodynamics in a fixed background (black hole spacetime), while DH completes the derivation of the complete set of GRMHD equations.

This paper presents a derivation of the GRMHD equations from the generalized Stokes Theorem (MTW; see also Page & Thorne, 1974), and was motivated by a derivation due to Clarke (1996) of the equations of non-relativistic MHD as discretized for the ZEUS code. Clarke provides an integral formulation of the equations of MHD using Stokes Theorem, and clearly shows the connection between the apparently simplistic finite-differencing techniques used in ZEUS (and also in the GRMHD code) to the notion of flux conservation embodied in Stokes Theorem.

2 Conservation Laws of GRMHD

The state of an ideal magnetized fluid on a curved background is described by a set of conservation laws. The equations in differential form are

$$\nabla_\mu (\rho U^\mu) = 0 \quad (\text{continuity}), \quad (1)$$

$$\nabla_\mu T^{\mu\nu} = 0 \quad (\text{energy} - \text{momentum}), \quad (2)$$

$$\nabla_\mu {}^*F^{\mu\nu} = 0 \quad (\text{induction}), \quad (3)$$

where ∇_μ is the covariant derivative, ρ is the density, U^μ the 4-velocity, $T^{\mu\nu}$ the energy-momentum tensor, $F^{\mu\nu}$ the electromagnetic field strength tensor, and its dual is

$${}^*F^{\mu\nu} = \frac{1}{2} \epsilon^{\mu\nu\delta\gamma} F_{\delta\gamma}, \quad (4)$$

where $\epsilon^{\mu\nu\delta\gamma} = -(1/\sqrt{-g}) [\mu\nu\delta\gamma]$ is the contravariant form of the Levi-Civita tensor. The energy-momentum tensor is

$$T^{\mu\nu} = \rho h U^\mu U^\nu + P g^{\mu\nu} + \frac{1}{4\pi} \left(F^\mu{}_\alpha F^{\nu\alpha} - \frac{1}{4} F_{\alpha\beta} F^{\alpha\beta} g^{\mu\nu} \right). \quad (5)$$

where $h = 1 + \epsilon + P/\rho$ is the specific enthalpy, with ϵ the specific internal energy and $P = \rho \epsilon (\Gamma - 1)$ the ideal gas pressure (Γ is the adiabatic exponent).

Following Lichnerowicz (1967) and Anile (1989), define the magnetic induction and the electric field by projecting onto the four-velocity,

$$B^\mu = {}^*F^{\mu\nu} U_\nu, \quad (6)$$

$$E^\mu = F^{\mu\nu} U_\nu. \quad (7)$$

The flux-freezing condition, wherein the electric field in the fluid rest frame is zero, implies $F^{\mu\nu} U_\nu = 0$. Combine the definition of the magnetic induction (6) with (4) and flux freezing to obtain

$$F_{\mu\nu} = \epsilon_{\alpha\beta\mu\nu} B^\alpha U^\beta, \quad (8)$$

where $\epsilon_{\mu\nu\delta\gamma} = \sqrt{-g} [\mu\nu\delta\gamma]$. The orthogonality condition

$$B^\mu U_\mu = 0 \quad (9)$$

follows directly from (6) and the anti-symmetry of $F^{\mu\nu}$.

Using these results, it is possible to rewrite the electromagnetic portion of the energy-momentum tensor to obtain

$$T^{\mu\nu} = \left(\rho h + \|b\|^2 \right) U^\mu U^\nu + \left(P + \frac{\|b\|^2}{2} \right) g^{\mu\nu} - b^\mu b^\nu \quad (10)$$

where $\|b\|^2 = b^\mu b_\mu$ is the magnetic field intensity, and $b^\mu = B^\mu/(4\pi)$ is the magnetic field four-vector.

In addition, we make the identification

$$\mathcal{B}^r = F_{\phi\theta}, \mathcal{B}^\theta = F_{r\phi}, \mathcal{B}^\phi = F_{\theta r}, \quad (11)$$

where $\mathcal{B}^j$ are the Constrained Transport (CT; Evans & Hawley, 1988) magnetic field variables. Also,

$$\begin{aligned} F_{tr} &= V^\phi \mathcal{B}^\theta - V^\theta \mathcal{B}^\phi = \mathcal{E}^r, \\ F_{t\theta} &= V^r \mathcal{B}^\phi - V^\phi \mathcal{B}^r = \mathcal{E}^\theta, \\ F_{t\phi} &= V^\theta \mathcal{B}^r - V^r \mathcal{B}^\theta = \mathcal{E}^\phi, \end{aligned} \quad (12)$$

where $\mathcal{E}^i$ are the CT EMFs.

3 Stokes Theorem

The generalized form of Stokes Theorem (MTW) relates the divergence of a vector field ($\mathcal{A}^\mu$) in a 4-volume ($\mathcal{V}$) to the flux of this vector field through the oriented surface ($\partial\mathcal{V}$) bounding this volume:

$$\int_{\mathcal{V}} \nabla_\mu \mathcal{A}^\mu d^4\Omega = \int_{\partial\mathcal{V}} \mathcal{A}^\mu d^3\Sigma_\mu \quad (13)$$

where $d^4\Omega$ is the volume element of $\mathcal{V}$ and $d^3\Sigma_\mu$ is the four-vector outward normal to the surface $\partial\mathcal{V}$. Since the GRMHD code uses the Boyer-Lindquist coordinates for the Kerr metric, the time and space coordinates (t, r, θ, ϕ) will be used from hereon. In Boyer-Lindquist coordinates, the volume element is $d^4\Omega = \sqrt{-g} dt dr d\theta d\phi$ where $\sqrt{-g} = \alpha \sqrt{\gamma}$, $\alpha = (-g^{tt})^{-1/2}$ is the lapse function, and $\sqrt{\gamma}$ is the determinant of the spatial 3-metric.

Expression (13) is completely general; in anticipation of its application to the GRMHD code, take the four-volume $\mathcal{V}$ to be an infinitesimal region whose geometry matches that of a discrete $3+1D$ zone in the computational grid. This four-volume has eight well defined boundary planes, corresponding to hypersurfaces where one the the Boyer-Linquist coordinates is held constant. Figure 1 presents a three-dimensional

sketch of the bounding faces, and only the bounding faces in the radial direction are labelled. The surface denoted r_0 represents the hypersurface of constant $r = r_0$, the “lower” bounding hypersurface of $\mathcal{V}$ in the radial direction. The surface denoted $r_0 + dr$ represents the hypersurface of constant $r = r_0 + dr$, the “upper” bounding hypersurface of $\mathcal{V}$ in the radial direction. Similarly, the hypersurfaces of constant polar angle are denoted θ_0 and $\theta_0 + d\theta$; and hypersurfaces of constant azimuthal angle, ϕ_0 and $\phi_0 + d\phi$. The generalized form of Stokes Theorem also deals with the time coordinate on an equal footing, so there are also surfaces of constant time, t_0 and $t_0 + dt$, bounding $\mathcal{V}$.

Figure 1: Sketch of hypersurfaces bounding the four-dimensional volume $\mathcal{V}$.

Figure 1 also introduces some additional terminology for the staggered mesh used in the GRMHD code: scalar quantities (e.g. ρ) reside on zone centres, whereas vector quantities (e.g. $\mathcal{B}^i$) reside on boundary surfaces (zone faces). In addition, the discrete grid associates the face-centred quantities to the “lower” bounding hypersurface (e.g. $\mathcal{B}^r$ associated with the zone of Figure 1 lies on the centre of the r_0 hypersurface, while the $\mathcal{B}^r$ on the $r_0 + dr$ hypersurface is associated with the next zone in the radial direction).

4 Discretizing the Integral Equations

The discretization of the integral form of the equations of GRMHD can be illustrated by considering a conservation law for some arbitrary vector field, $\nabla_\mu \mathcal{A}^\mu = 0$, which can be expressed using Stokes Theorem (13) as an integral over $\partial\mathcal{V}$:

$$\int_{\partial\mathcal{V}} \mathcal{A}^\mu d^3\Sigma_\mu = 0. \quad (14)$$

Using the geometry of volume $\mathcal{V}$ introduced in the previous section, the conservation law reads,

$$0 = \int_{\partial\mathcal{V}} \mathcal{A}^\mu d^3\Sigma_\mu = \int_{r_0+dr} \mathcal{A}^r \sqrt{-g} dt d\theta d\phi - \int_{r_0} \mathcal{A}^r \sqrt{-g} dt d\theta d\phi \quad (15)$$

$$\begin{aligned}
& + \int_{\theta_0+d\theta} \mathcal{A}^\theta \sqrt{-g} dt dr d\phi - \int_{\theta_0} \mathcal{A}^\theta \sqrt{-g} dt dr d\phi \\
& + \int_{\phi_0+d\phi} \mathcal{A}^\phi \sqrt{-g} dt dr d\theta - \int_{\phi_0} \mathcal{A}^\phi \sqrt{-g} dt dr d\theta \\
& + \int_{t_0+dt} \mathcal{A}^t \sqrt{-g} dr d\theta d\phi - \int_{t_0} \mathcal{A}^t \sqrt{-g} dr d\theta d\phi
\end{aligned}$$

where the subscript on each integral indicates the specific hypersurface (see Figure 1), and each integral symbol is understood to represent a definite triple integral over each bounding hypersurface.

The presence of the time coordinate in the integrals over surfaces of constant spatial coordinate serves as a pointed reminder that proper centering of physical quantities must be done not only in space but in time as well. If for no other reason, the natural emergence of this important connection between all four coordinates validates the use of the integral formulation as the starting point for numerical discretization.

In going to a discrete grid, letting $dx^\mu \rightarrow \Delta x^\mu$, (15) becomes an approximate relation, and there are many possible ways to proceed with the discretization. To see how this comes about, consider the flux of $\mathcal{A}^\mu$ through the surface of constant r_0 ,

$$\int_{r_0} \mathcal{A}^r \sqrt{-g} dt d\theta d\phi \equiv \left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \int_{t_0}^{t_0+\Delta t} \mathcal{A}^r \sqrt{-g} dt d\theta d\phi \right\}_{r_0} \quad (16)$$

In subsequent expressions, the braces $\{ \}$ will denote a given hypersurface; this notation is similar to that used by Page & Thorne (1974). Neglecting the integral over time for a moment, the simplest approximation to (16) is the product of the mean radial component of $\mathcal{A}$ on the surface multiplied by the area of the surface,

$$\left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \mathcal{A}^r \sqrt{-g} d\theta d\phi \right\}_{r_0} \approx \langle \mathcal{A}^r \rangle_{r_0} \left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \sqrt{-g} d\theta d\phi \right\}_{r_0}, \quad (17)$$

where $\langle \mathcal{A}^r \rangle_{r_0}$ represents the mean value of $\mathcal{A}^r$ on the hypersurface r_0 . On a discrete grid, the flux could be approximated by taking quantities on the zone face as representative of this mean so that

$$\left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \mathcal{A}^r \sqrt{-g} d\theta d\phi \right\}_{r_0} \approx \{ \mathcal{A}^r \sqrt{-g} \Delta\theta \Delta\phi \}_{r_0}, \quad (18)$$

where $\mathcal{A}^r$ and $\sqrt{-g}$ on the right-hand side are understood to be evaluated at the centre of the r_0 zone face.

However, equation (16) also includes the integral over time which must be dealt with in a consistent manner. In a numerical implementation, the solution at time level t_0 is known and the solution at time level $t_0 + \Delta t$ is what is sought, so (16) cannot be evaluated exclusively with data at the known time level t_0 without introducing potentially serious numerical errors. For consistency, (16) should be evaluated in such

a way as to involve the unknown time level. For example, a complete discretization of (16) could be written as

$$\left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \int_{t_0}^{t_0+\Delta t} \mathcal{A}^r \sqrt{-g} dt d\theta d\phi \right\}_{r_0} \approx \frac{1}{2} \left\{ \left[\mathcal{A}^{r(n)} + \mathcal{A}^{r(n+1)} \right] \sqrt{-g} \Delta t \Delta\theta \Delta\phi \right\}_{r_0}, \quad (19)$$

where solutions at different time levels are distinguished by introducing superscripts; $\mathcal{A}^{r(n)}$ denotes the value of $\mathcal{A}^r$ at the current time t_0 , and $\mathcal{A}^{r(n+1)}$ at the next time level, $t_0 + \Delta t$.

Similar expressions can be derived for the other hypersurfaces of constant spatial coordinate. This leaves the two hypersurfaces of constant time. Take the surface of constant t_0 , the flux through this surface is

$$\int_{t_0} \mathcal{A}^t \sqrt{-g} dr d\theta d\phi \equiv \left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \int_{r_0}^{r_0+\Delta r} \mathcal{A}^t \sqrt{-g} dr d\theta d\phi \right\}_{t_0}, \quad (20)$$

which can be approximated as

$$\left\{ \int_{\phi_0}^{\phi_0+\Delta\phi} \int_{\theta_0}^{\theta_0+\Delta\theta} \int_{r_0}^{r_0+\Delta r} \mathcal{A}^t \sqrt{-g} dr d\theta d\phi \right\}_{t_0} \approx \mathcal{A}^{t(n)} \sqrt{-g} \Delta r \Delta\theta \Delta\phi. \quad (21)$$

Note that for the hypersurfaces of constant time, the brace notation is not used, and the time-components of vectors are taken to be zone-centred quantities.

Combining all these terms, and, in keeping with the GRMHD code, taking Δt to be constant over the entire grid, at all times, (15) can be approximated as

$$\begin{aligned} 0 \approx & \frac{\mathcal{A}^{t(n+1)} - \mathcal{A}^{t(n)}}{\Delta t} + \frac{1}{2\sqrt{-g}} \\ & \times \left(\frac{\left\{ \sqrt{-g} \left[\mathcal{A}^{r(n+1)} + \mathcal{A}^{r(n)} \right] \right\}_{r_0+\Delta r} - \left\{ \sqrt{-g} \left[\mathcal{A}^{r(n+1)} + \mathcal{A}^{r(n)} \right] \right\}_{r_0}}{\Delta r} \right. \\ & + \frac{\left\{ \sqrt{-g} \left[\mathcal{A}^{\theta(n+1)} + \mathcal{A}^{\theta(n)} \right] \right\}_{\theta_0+\Delta\theta} - \left\{ \sqrt{-g} \left[\mathcal{A}^{\theta(n+1)} + \mathcal{A}^{\theta(n)} \right] \right\}_{\theta_0}}{\Delta\theta} \\ & \left. + \frac{\left\{ \sqrt{-g} \left[\mathcal{A}^{\phi(n+1)} + \mathcal{A}^{\phi(n)} \right] \right\}_{\phi_0+\Delta\phi} - \left\{ \sqrt{-g} \left[\mathcal{A}^{\phi(n+1)} + \mathcal{A}^{\phi(n)} \right] \right\}_{\phi_0}}{\Delta\phi} \right). \end{aligned} \quad (22)$$

Of course, this is but one possible discretization of (15). The advantage of the integral formulation is that it facilitates writing flux-conserving numerical routines which achieve proper centering not only in space but in time as well. When working with a differential formulation of the conservation laws, such choices may not be as obvious.

5 Equations of GRMHD in Integral Form

The numerical solutions to the equations of GRMHD follow the time-evolution of a fluid on a 3D spatial grid from some prescribed initial state at some Boyer-Lindquist time t_i . The numerical solver advances the solution in small, uniform increments Δt and produces a time-ordered sequence of states for the fluid.

The integral form of the GRMHD equations is

$$\begin{aligned} \int_{\mathcal{V}} \nabla_{\mu} (\rho U^{\mu}) d^4\Omega &= 0 = \int_{\partial\mathcal{V}} (\rho U^{\mu}) d^3\Sigma_{\mu}, \\ \int_{\mathcal{V}} \nabla_{\mu} T^{\mu\nu} d^4\Omega &= 0 = \int_{\partial\mathcal{V}} T^{\mu\nu} d^3\Sigma_{\mu}, \\ \int_{\mathcal{V}} \nabla_{\mu} {}^*F^{\mu\nu} d^4\Omega &= 0 = \int_{\partial\mathcal{V}} {}^*F^{\mu\nu} d^3\Sigma_{\mu}. \end{aligned} \tag{23}$$

As in the previous sections, these equations will be discretized by taking the volume $\mathcal{V}$ to represent a zone on the computational grid.

The previous section showed how an implicit scheme could be obtained from Stokes Theorem. Instead of using such a scheme, the GRMHD code approximates the temporal integrals by building an approximate, upwinded solution at an intermediate time level; this approach gives rise to an explicit scheme that is computationally simpler. An additional motivation is that the conservation laws involve a mix of scalar and vectorial code variables which must be properly centred. For example, to achieve proper centring in time and space in the case of the equation of continuity, the product of density ρ (zone-centred) and four-velocity U^{μ} (face-centred) is evaluated by upwinding the density, i.e. by interpolating density to the appropriate zone face and advancing it in time to the intermediate time level, $n + 1/2$. This estimate, at the half-step, is then used in the continuity equation. Denote the upwinded quantity using an overbar; for instance, radially upwinded density would be shown as $\bar{\rho}^r U^r$.

The details of the upwinding technique are not relevant to the present discussion, as they simply represent an explicit means of achieving proper time-centring of the integrals over the time coordinate in (23). A description of the technique as it applies to the GRMHD code can be found in DH and in HSW.

5.1 Continuity

The integral form of the continuity equation is

$$\int_{\partial\mathcal{V}} (\rho U^\mu) d^3\Sigma_\mu = 0. \quad (24)$$

Using the geometry of volume $\mathcal{V}$ introduced earlier, the equation reads,

$$\begin{aligned} 0 &= \int_{r_0+dr} (\rho U^r) \sqrt{-g} dt d\theta d\phi - \int_{r_0} (\rho U^r) \sqrt{-g} dt d\theta d\phi \\ &+ \int_{\theta_0+d\theta} (\rho U^\theta) \sqrt{-g} dt dr d\phi - \int_{\theta_0} (\rho U^\theta) \sqrt{-g} dt dr d\phi \\ &+ \int_{\phi_0+d\phi} (\rho U^\phi) \sqrt{-g} dt dr d\theta - \int_{\phi_0} (\rho U^\phi) \sqrt{-g} dt dr d\theta \\ &+ \int_{t_0+dt} (\rho U^t) \sqrt{-g} dr d\theta d\phi - \int_{t_0} (\rho U^t) \sqrt{-g} dr d\theta d\phi. \end{aligned} \quad (25)$$

Using the upwinding notation we have, for example,

$$\int_{r_0} (\rho U^r) \sqrt{-g} dt d\theta d\phi \approx \{\bar{\rho}^r U^r \sqrt{-g} \Delta t \Delta \theta \Delta \phi\}_{r_0}. \quad (26)$$

Using the definitions of transport velocity, $U^\mu = V^\mu W/\alpha$, and auxiliary density, $D = \rho W$, this result is rewritten

$$\int_{r_0} (\rho U^r) \sqrt{-g} dt d\theta d\phi \approx \{\bar{D}^r V^r \sqrt{\gamma} \Delta t \Delta \theta \Delta \phi\}_{r_0}. \quad (27)$$

The integrals through the hypersurfaces of constant t are approximated as

$$\int_{t_0+dt} (\rho U^t) \sqrt{-g} dr d\theta d\phi - \int_{t_0} (\rho U^t) \sqrt{-g} dr d\theta d\phi \approx [D^{(n+1)} - D^{(n)}] \sqrt{\gamma} \Delta r \Delta \theta \Delta \phi \quad (28)$$

Combining these results and simplifying yields

$$\begin{aligned} \frac{D^{(n+1)} - D^{(n)}}{\Delta t} &= -\frac{1}{\sqrt{\gamma}} \left[\frac{\{\sqrt{\gamma} \bar{D}^r V^r\}_{r_0+\Delta r} - \{\sqrt{\gamma} \bar{D}^r V^r\}_{r_0}}{\Delta r} \right. \\ &+ \frac{\{\sqrt{\gamma} \bar{D}^\theta V^\theta\}_{\theta_0+\Delta \theta} - \{\sqrt{\gamma} \bar{D}^\theta V^\theta\}_{\theta_0}}{\Delta \theta} \\ &\left. + \frac{\{\sqrt{\gamma} \bar{D}^\phi V^\phi\}_{\phi_0+\Delta \phi} - \{\sqrt{\gamma} \bar{D}^\phi V^\phi\}_{\phi_0}}{\Delta \phi} \right] \end{aligned} \quad (29)$$

which is the discretized, upwinded form of equation (24) in DH as implemented in the GRMHD code, recovered very simply here by the integral formulation of the equation of continuity. Note how this approach “breaks” the implicit coupling at the unknown time level on the left- and right-hand sides shown in (22), and achieves proper centering through an explicit method.

5.2 Induction

The integral form of the induction equation is

$$\int_{\partial\mathcal{V}} {}^*F^{\mu\nu} d^3\Sigma_\mu = 0. \quad (30)$$

Using the geometry of volume $\mathcal{V}$ introduced earlier, the four components of the induction equation are,

$$\begin{aligned} 0 = \int_{\partial\mathcal{V}} {}^*F^{\mu\nu} d^3\Sigma_\mu &= \int_{r_0+dr} {}^*F^{r\nu} \sqrt{-g} dt d\theta d\phi - \int_{r_0} {}^*F^{r\nu} \sqrt{-g} dt d\theta d\phi \\ &+ \int_{\theta_0+d\theta} {}^*F^{\theta\nu} \sqrt{-g} dt dr d\phi - \int_{\theta_0} {}^*F^{\theta\nu} \sqrt{-g} dt dr d\phi \\ &+ \int_{\phi_0+d\phi} {}^*F^{\phi\nu} \sqrt{-g} dt dr d\theta - \int_{\phi_0} {}^*F^{\phi\nu} \sqrt{-g} dt dr d\theta \\ &+ \int_{t_0+dt} {}^*F^{t\nu} \sqrt{-g} dr d\theta d\phi - \int_{t_0} {}^*F^{t\nu} \sqrt{-g} dr d\theta d\phi. \end{aligned} \quad (31)$$

Though the previous examples did not deal with tensor quantities, the results are readily extended. Taking the time component, $\nu = t$, the integrals over the surfaces of constant t are identically zero (antisymmetry of $F^{\mu\nu}$), leaving

$$\begin{aligned} 0 = \int_{\partial\mathcal{V}} {}^*F^{\mu t} d^3\Sigma_\mu &= \int_{r_0+dr} {}^*F^{rt} \sqrt{-g} dt d\theta d\phi - \int_{r_0} {}^*F^{rt} \sqrt{-g} dt d\theta d\phi \\ &+ \int_{\theta_0+d\theta} {}^*F^{\theta t} \sqrt{-g} dt dr d\phi - \int_{\theta_0} {}^*F^{\theta t} \sqrt{-g} dt dr d\phi \\ &+ \int_{\phi_0+d\phi} {}^*F^{\phi t} \sqrt{-g} dt dr d\theta - \int_{\phi_0} {}^*F^{\phi t} \sqrt{-g} dt dr d\theta. \end{aligned} \quad (32)$$

Using (4) and substituting the expressions for the CT variables, (11) and (12), back into (32) yields:

$$\begin{aligned} 0 &= \int_{r_0+dr} \mathcal{B}^r dt d\theta d\phi - \int_{r_0} \mathcal{B}^r dt d\theta d\phi \\ &+ \int_{\theta_0+d\theta} \mathcal{B}^\theta dt dr d\phi - \int_{\theta_0} \mathcal{B}^\theta dt dr d\phi \\ &+ \int_{\phi_0+d\phi} \mathcal{B}^\phi dt dr d\theta - \int_{\phi_0} \mathcal{B}^\phi dt dr d\theta. \end{aligned} \quad (33)$$

To discretize this result, note that the vanishing of the integrals over hypersurfaces of constant t indicates that this relation must be satisfied *at all times*; this component of the induction equation is a constraint on the CT magnetic field. Equation (33) simplifies to:

$$0 \approx \frac{\{\mathcal{B}^r\}_{r_0+\Delta r} - \{\mathcal{B}^r\}_{r_0}}{\Delta r} + \frac{\{\mathcal{B}^\theta\}_{\theta_0+\Delta\theta} - \{\mathcal{B}^\theta\}_{\theta_0}}{\Delta\theta} + \frac{\{\mathcal{B}^\phi\}_{\phi_0+\Delta\phi} - \{\mathcal{B}^\phi\}_{\phi_0}}{\Delta\phi}, \quad (34)$$

which is the familiar “div B” constraint on the magnetic field, and equivalent to equation (47) of DH.

The spatial components of the induction equation describe the time-evolution of the CT magnetic field. To see how this comes about, take the radial component, $\nu = r$, of the induction equation. The integrals over the surfaces of constant r are identically zero, leaving

$$\begin{aligned} 0 &= \int_{\theta_0+d\theta}^{\theta_0} {}^*F^{\theta r} \sqrt{-g} dt dr d\phi - \int_{\theta_0}^{\theta_0+d\theta} {}^*F^{\theta r} \sqrt{-g} dt dr d\phi \\ &+ \int_{\phi_0+d\phi}^{\phi_0} {}^*F^{\phi r} \sqrt{-g} dt dr d\theta - \int_{\phi_0}^{\phi_0+d\phi} {}^*F^{\phi r} \sqrt{-g} dt dr d\theta \\ &+ \int_{t_0+dt}^{t_0} {}^*F^{tr} \sqrt{-g} dr d\theta d\phi - \int_{t_0}^{t_0+dt} {}^*F^{tr} \sqrt{-g} dr d\theta d\phi. \end{aligned} \quad (35)$$

Using (4), (11), and (12), equation (35) can be discretized and rearranged to read

$$0 \approx \frac{\mathcal{B}^{r(n+1)} - \mathcal{B}^{r(n)}}{\Delta t} + \frac{\{\bar{\mathcal{E}}^\phi\}_{\theta_0+\Delta\theta} - \{\bar{\mathcal{E}}^\phi\}_{\theta_0}}{\Delta\theta} - \frac{\{\bar{\mathcal{E}}^\theta\}_{\phi_0+\Delta\phi} - \{\bar{\mathcal{E}}^\theta\}_{\phi_0}}{\Delta\phi} \quad (36)$$

Similar rearrangements can be made for the θ and ϕ components of (31)

$$0 \approx \frac{\mathcal{B}^{\theta(n+1)} - \mathcal{B}^{\theta(n)}}{\Delta t} - \frac{\{\bar{\mathcal{E}}^\phi\}_{r_0+\Delta r} - \{\bar{\mathcal{E}}^\phi\}_{r_0}}{\Delta r} + \frac{\{\bar{\mathcal{E}}^r\}_{\phi_0+\Delta\phi} - \{\bar{\mathcal{E}}^r\}_{\phi_0}}{\Delta\phi} \quad (37)$$

$$0 \approx \frac{\mathcal{B}^{\phi(n+1)} - \mathcal{B}^{\phi(n)}}{\Delta t} + \frac{\{\bar{\mathcal{E}}^\theta\}_{r_0+\Delta r} - \{\bar{\mathcal{E}}^\theta\}_{r_0}}{\Delta r} - \frac{\{\bar{\mathcal{E}}^r\}_{\theta_0+\Delta\theta} - \{\bar{\mathcal{E}}^r\}_{\theta_0}}{\Delta\theta} \quad (38)$$

These expressions are formally equivalent to the CT equations of DH (cf. equation (34) in DH). However, as with the continuity equation, the issue of proper time-centering, this time of the EMFs, is important. This is flagged in the above expressions by using an overbar, $\bar{\mathcal{E}}$, on the EMFs.

Evans & Hawley (1988) discussed the issue of time-centering of the EMFs, noting that there seemed to be some flexibility to the prescription of the EMFs. DH provided a derivation of a numerical formulation similar to the MOCCT approach of Hawley & Stone (1995) to provide time-centred expressions which were stable under a variety of numerical tests. Perhaps the main advantage of revisiting CT from the point of view of Stokes Theorem is that this formulation makes it more obvious that proper centering, both in space and time, is indeed required. A prescription for EMFs that is compatible with the integral formulation has the EMFs edge-centred on the spatial grid and centred on the half-step on the temporal grid. The approximation using incompressible MHD documented in DH is but one possible realization of this. Of course, implicit formulations of (31) are also possible, but are likely to be difficult to implement.

5.3 Energy-Momentum Conservation

The integral form of the energy-momentum conservation equations,

$$\int_{\partial\mathcal{V}} T^{\mu\nu} d^3\Sigma_\mu = 0 \quad (39)$$

Using the geometry of volume $\mathcal{V}$ introduced earlier, the four components of the energy-momentum equation are,

$$\begin{aligned} 0 = \int_{\partial\mathcal{V}} T^{\mu\nu} d^3\Sigma_\mu &= \int_{r_0+dr} T^{r\nu} \sqrt{-g} dt d\theta d\phi - \int_{r_0} T^{r\nu} \sqrt{-g} dt d\theta d\phi \\ &+ \int_{\theta_0+d\theta} T^{\theta\nu} \sqrt{-g} dt dr d\phi - \int_{\theta_0} T^{\theta\nu} \sqrt{-g} dt dr d\phi \\ &+ \int_{\phi_0+d\phi} T^{\phi\nu} \sqrt{-g} dt dr d\theta - \int_{\phi_0} T^{\phi\nu} \sqrt{-g} dt dr d\theta \\ &+ \int_{t_0+dt} T^{t\nu} \sqrt{-g} dr d\theta d\phi - \int_{t_0} T^{t\nu} \sqrt{-g} dr d\theta d\phi. \end{aligned} \quad (40)$$

The discretization of this set of equations proceeds as described above. The only issue is the relation between the primitive code variables and $T^{\mu\nu}$, and the extraction of the primitive variables.

In the GRMHD code, the energy-momentum conservation law is treated differently, and the resulting equations provide a so-called non-conservative treatment of energy. The conservation law $\nabla_\mu T^{\mu\nu} = 0$ is applied to a fluid with four-velocity U^μ . A very convenient reformulation of the conservation law arises when one “reorients” the equations into a component parallel to the local four-velocity and components orthogonal to it (MTW). Projection onto the four-velocity yields a scalar relation,

$$U_\nu \nabla_\mu T^{\mu\nu} = 0, \quad (41)$$

which, as shown in HSW and DH, leads to the equation of internal energy conservation,

$$\partial_t (E) + \frac{1}{\sqrt{\gamma}} \partial_i (\sqrt{\gamma} E V^i) + P \partial_t (W) + \frac{P}{\sqrt{\gamma}} \partial_i (\sqrt{\gamma} W V^i) = 0. \quad (42)$$

To obtain the components of the conservation law orthogonal to the four-velocity, use the projection tensor $P_{\mu\nu} = g_{\mu\nu} + U_\mu U_\nu$,

$$P_{\alpha\nu} \nabla_\mu T^{\mu\nu} = g_{\alpha\nu} \nabla_\mu T^{\mu\nu} + U_\alpha U_\nu \nabla_\mu T^{\mu\nu} = \nabla_\mu T^\mu{}_\alpha = 0, \quad (43)$$

where the final result was obtained by commuting the metric with the covariant derivative and also using (41). As shown in DH, the three spatial components of this equation are

$$\begin{aligned} 0 &= \partial_t (S_j - \alpha b_j b^t) \\ &+ \frac{1}{\sqrt{\gamma}} \partial_i \sqrt{\gamma} (S_j V^i - \alpha b_j b^i) + \frac{1}{2} \left(\frac{S_\epsilon S_\mu}{S^t} - \alpha b_\mu b^\epsilon \right) \partial_j g^{\mu\epsilon} + \alpha \partial_j \left(P + \frac{\|b\|^2}{2} \right). \end{aligned} \quad (44)$$

The time-component is not used; instead, the GRMHD code uses the normalization condition

$$g^{\mu\nu} S_\mu S_\nu = - \left[(\rho h + \|b\|^2) W \right]^2 \quad (45)$$

to close the set of equations.

6 Summary and Discussion

This paper has outlined the development of discretized equations of ideal General Relativistic Magnetohydrodynamics (GRMHD) from the integral form of the conservation laws. Stokes Theorem transforms the conservation laws of GRMHD into simple flux integrals through the boundary of a closed four-volume, and many possible discretizations are possible for these integrals. The particular choices used in the GRMHD code for the equation of continuity and the induction equation represent but one implementation, arguably the simplest and most straightforward of these. Many other possible implementations are implied by equations (25) and (31). The GRMHD code uses an alternate discretization of the energy-momentum conservation equation; the integral formulation discussed here, (40), offers another possible discretization in keeping with the treatment of the continuity and induction equations. A note of caution is in order: the integral relations derived here, dealing as they do with coupled sets of non-linear equations, may not yield stable numerical schemes. Since only limited stability analysis is possible in non-linear differential equations, theoretical work must be complemented by careful development and testing to validate any particular numerical treatment.

In addition, this discussion has implicitly assumed smooth flows; the issue of shock capturing has not been touched upon. The GRMHD code uses a relativistic treatment that is based on the original Von Neumann & Richtmyer (1950) artificial viscosity treatment, a relativistic extension of this technique by May & White (1967), and HSW. This remains the state of the art as of this writing.

As a final note, the zone-based, flux-conserving formulation discussed here may also be of benefit in treating boundary conditions. The boundary zones, or ghost zones, of the computational grid are used to impose physical boundary conditions on the computational volume and also to provide approximate data used by the interpolation routines to provide correct time-centering of zones on the computational grid adjacent to the physical boundaries. The main interest in the integral formulation of boundary data lies at the inner radial boundary, where frame dragging effects are important, and also at the difficult “corner zones” which sit just outside the pole caps of the black hole. Definitive statements regarding the flux of electromagnetic energy near the event horizon hinge on reliable boundary treatments, and it is hoped that a more sophisticated approach, based on the integral formulation discussed here, may help. This remains an open area of research.
